We derive  $H(\textit{curl})$ -error estimates and improved  $L2$ -error estimates for the Maxwell equations. These estimates only invoke the expected regularity pickup of the exact solution in the scale of the Sobolev spaces, which is typically lower than  $1/2$  and can be arbitrarily close to  $0$  when the material properties are heterogeneous. The key tools for the analysis are commuting quasi-interpolation operators in  $H(\textit{curl})$ - and  $H(\textit{div})$ -conforming finite element spaces and, most crucially, newly-devised quasi-interpolation operators delivering optimal estimates on the decay rate of the best-approximation error for functions with Sobolev regularity index arbitrarily close to  $0$ . The proposed analysis entirely bypasses the technique known in the literature as the discrete compactness argument.

This is joint work with Jean-Luc Guermond (Texas A&M University).
